From Output to Input: Modeling the Reverse Prompt Engineering Problem

David Busbib Yehuda Frist Yarin Ohayon

July 30, 2025

Abstract

This research proposal investigates the novel concept of Reverse Prompt Engineering, which aims to reconstruct the original prompts that generated specific outputs from language models. By treating outputs as clues to their generative origins, this work contributes to efforts in model interpretability, auditability, and safety. We propose a formulation of the task, using aligned instruction-output pairs to train encoder-decoder models capable of prompt reconstruction. This direction complements recent model-agnostic approaches and offers new perspectives on the alignment between human intent and machine behavior.

1 Introduction

Large language models (LLMs) have demonstrated remarkable proficiency in generating coherent and contextually appropriate outputs in response to natural language instructions [LZY23, ZDL+23]. As these systems become integral to a range of applications, from question answering to creative writing, attention has increasingly turned to the interpretability of their outputs. Understanding how a model arrives at a given response is a central challenge in responsible AI [MZC+23]. One promising direction within this broader agenda is reverse prompt engineering — the task of inferring the original prompt or instruction that led to an observed output [ZCI23].

This inverse formulation of language generation is not only cognitively intuitive, akin to deducing questions from answers, but also carries significant practical value. By recovering the intent behind an output, we gain tools for auditing model behavior, detecting prompt leakage, and tracing the provenance of generated content. Moreover, reverse prompting offers insight into how models encode and preserve instructional information, contributing to our understanding of how language models generalize across tasks [NFM+25, LJD+24].

In this work, we formalize reverse prompt engineering as a supervised sequence-to-sequence task. We leverage the Alpaca dataset, comprising over 50,000 instruction-output pairs generated via OpenAI's `text-davinci-003` model to train encoder-decoder models capable of predicting prompts from responses. Our goal is not only to reconstruct natural instructions with high semantic fidelity but also to evaluate how well the reconstructed prompts elicit outputs aligned with the originals.

2 Related Work

Recent work such as [LK24] introduced a black-box, training-free framework that employs a genetic algorithm-inspired search to recover prompts by maximizing semantic similarity with outputs, an approach that is model-agnostic but computationally intensive. In contrast, our method is supervised and data-driven, leveraging the alignment within instruction-following datasets like Alpaca to train models capable of generalizing across prompt types. This direction parallels reversible prompt tuning [HSS+22], where T5 is trained to generate prompts from task outputs, underscoring the inherent bidirectionality of instruction-based modeling.

3 Data

Our study is grounded in the Alpaca dataset [TGZ+23], a publicly released collection of 52,000 instruction-following examples generated using OpenAI's `text-davinci-003` model. Each instance consists of a triplet: an

instruction specifying the task, an optional input providing context, and the corresponding model-generated output.

To align the dataset to our given task, we reformat each example into a supervised training pair where the output serves as the input to the model and the instruction becomes the target. The optional input field, present in only a minority of cases, is appended to the original input. Additional preprocessing steps include removal of uninformative examples and truncation to satisfy model constraints. This reformulation enables the model to learn prompt recovery from the generated content alone, reflecting the core inversion at the heart of the task.

4 Methods

To model the reverse prompt engineering task, we fine-tune a pre-trained T5 base [RSR+20] on the preprocessed Alpaca dataset. The model is trained to map generated outputs (serving as inputs) to their corresponding instructions (serving as targets), thereby learning to infer the original prompt from observed text. Training is carried out using Hugging Face's Trainer API. Following empirical tuning (see Figure 1), the optimal hyperparameters were determined to be a learning rate of 5e-5, a batch size of 4, weight decay of 0.01, and a warmup phase comprising 500 steps. Gradient accumulation over two steps was employed to simulate a larger effective batch size. The model was trained for three epochs with validation loss used to monitor convergence and mitigate overfitting. This configuration achieved a final training loss of 1.5518 and an evaluation loss of 1.317.

We evaluate our model against two baselines. The zero-shot baseline involves prompting google/flan-t5-base with a fixed instruction (appendix 1) asking it to infer the original prompt from a given output, without any task-specific tuning. The few-shot baseline augments this setup by providing google/flan-t5-base with 3 in-context examples of successful output-to-prompt mappings (appendix 2). These serve to contextualize the task and enable limited adaptation via demonstration. The model outputs are evaluated across a range of metrics designed to capture both surface-level similarity and deeper semantic alignment.

5 Results

Our model consistently outperforms both zero-shot and few-shot baselines across all major evaluation metrics(see Table 1) . It demonstrates markedly higher performance in text similarity measures such as BLEU, ROUGE, and METEOR, indicating improved alignment with the original prompts. Semantic similarity, as captured by BARTScore, also favors the fine-tuned model, suggesting more coherent and contextually appropriate reconstructions.In terms of semantic similarity, the fine-tuned model achieves the highest BARTScore, indicating greater alignment with the original prompts compared to both baselines. For perplexity, the few-shot model exhibits the lowest value, suggesting higher fluency under this metric, while the zero-shot model performs worst. MAUVE scores, which reflect distributional similarity to the original prompt distribution, are generally low across all models, with the zero-shot baseline achieving the highest score. Finally, Self-BLEU indicates that

Metric	Fine-Tuned T5 (Ours)	Zero-shot	Few-shot
BLEU	**0.2251**	0.0505	0.0644
ROUGE-1	**0.5257**	0.2493	0.2639
ROUGE-L	**0.4989**	0.2339	0.2437
METEOR	**0.4728**	0.1797	0.2021
BARTScore	**-2.667**	-3.8709	-3.7706
Perplexity	92.658	2797.0630	**52.9779**
MAUVE	0.0077	**0.0509**	0.0093
Self-BLEU	0.5223	**0.0786**	0.4824

Table 1: Resents average performance metrics across models, highlighting the superiority of the fine-tuned T5.

the fine-tuned and few-shot models generate less diverse outputs than the zero-shot baseline, which shows substantially higher output variability.

6 Analysis

6.1 Lexical Overlap and Surface Fidelity

The BLEU and ROUGE scores indicate a clear advantage for the fine-tuned model in capturing surface-level correspondence with the original prompts. BLEU, which measures n-gram precision, shows significantly higher values for the fine-tuned system, reflecting a greater capacity to reproduce local lexical patterns. ROUGE-1 and ROUGE-L metrics that incorporate recall and are sensitive to token ordering follow this trend, suggesting that the model is not only reproducing correct tokens but also doing so in the correct sequence. The comparatively low ROUGE scores of the baselines point to difficulties in maintaining structural coherence. The fine-tuned model, in contrast, appears more capable of retaining the syntactic scaffolding of original instructions, which is particularly important for prompts containing multiple clauses or compositional logic.

Beyond lexical fidelity, the METEOR metric suggests that our model also demonstrates improved semantic preservation. By incorporating synonymy, stemming, and paraphrastic flexibility, METEOR highlights cases where meaning is retained even when exact word matches differ. The large performance gap between our model and both baselines in this metric points to a genuine semantic advantage. BARTScore further supports this conclusion, offering a model-based evaluation of textual plausibility and contextual alignment. The fine-tuned model achieves the least negative BARTScore among the three, implying its outputs are more semantically coherent and contextually grounded than those of the baselines. This is particularly relevant in a task where reconstructed prompts must not only match the target in form, but also in communicative intent.

6.2 Fluency and Language Modeling Consistency

Perplexity results reveal a nuanced contrast between surface fluency and task-specific relevance. The few-shot baseline exhibits the lowest perplexity, consistent with its in-context generation from a highly fluent pretrained

model. The fine-tuned model, while more perplexing under a general language model, produces content more closely aligned with the ground truth prompts. The zero-shot configuration fares worst in both perplexity and accuracy metrics, suggesting that fluency in isolation is insufficient. These findings illustrate that in prompt reconstruction tasks, perplexity should be interpreted with caution: low perplexity may signal linguistic smoothness, but not necessarily fidelity to the underlying instruction.

6.3 Distributional Alignment and Output Diversity

MAUVE scores are uniformly low across all models, with only minor variation. While the zero-shot baseline achieves the highest score, the values are small enough to suggest that none of the models strongly align with the token-level distribution of the target prompts. This may reflect limitations of the metric in low-data or short-sequence regimes, or a genuine lack of stylistic convergence.

In contrast, Self-BLEU offers more actionable insight into model behavior. The fine-tuned model yields the highest Self-BLEU score, indicating lower output diversity and greater internal consistency. This is beneficial in our task, as it reflects a model that has learned a stable mapping from outputs to prompts without overgeneralizing. The few-shot model follows closely, while the zero-shot model displays substantially higher diversity, which in this case reflects variability at the expense of precision. Taken together, these results suggest that the fine-tuned model strikes a balance between diversity and determinism, generating prompts that are both consistent and accurate without degenerating into repetition.

7 Future Work

An important direction we initially intended to pursue involved closing the reconstruction loop: feeding the predicted prompts generated by our model back into the original language model, OpenAI's `text-davinci-003`, that produced the outputs in the Alpaca dataset. This would have enabled a more direct and grounded evaluation of reconstruction quality by comparing the original outputs with those elicited by the recovered prompts, thereby measuring functional equivalence rather than surface similarity alone. Unfortunately, access to `text-davinci-003` was deprecated, preventing us from conducting this evaluation.

Future work will focus on identifying a dataset generated by a non-deprecated instruction-tuned model, such as `gpt-3.5-turbo`, to enable round-trip evaluation—feeding reconstructed prompts back into the original model and comparing the resulting outputs. This functional assessment will complement current similarity metrics.

8 Limitations and Ethical Considerations

While this work demonstrates the feasibility of reverse prompt engineering, it also raises important limitations and ethical considerations. First, the task remains inherently ill-posed in cases where multiple plausible prompts could lead to similar outputs, challenging the notion of a single ground truth. This ambiguity limits the reliability of evaluation metrics and the interpretability of model predictions in open-ended contexts.

Moreover, the ability to infer prompts from outputs introduces potential risks related to privacy, intellectual property, and prompt leakage. In settings where prompts contain sensitive, proprietary, or user-specific information, successful reconstruction could be misused for surveillance, competitive inference, or model inversion attacks. As reverse prompting capabilities improve, it is essential to consider safeguards that mitigate such risks, including data anonymization, differential privacy techniques, and restrictions on model deployment in sensitive domains.

Appendix

Zero-shot Prompt

For the zero-shot baseline, we constructed a general-purpose instruction designed to elicit the original prompt from a given output without any prior examples. The prompt format is as follows:

```
Given this output, what prompt likely generated it?

Output: {example['input_text']}
Prompt:
```

Few-shot Prompt

For the few-shot baseline, we employed in-context learning by randomly sampling three diverse instruction-output pairs from the training data. This randomization strategy was used to avoid overfitting to specific prompt patterns and to encourage generalization. Each example included a context (if provided), the model-generated response, and the corresponding original instruction framed as a question.

Answer:
Context: `<no input>`
Response:

1. I've told you a million times.
2. She's as light as a feather.
3. His car is faster than lightning.

Question: Provide 3 examples of hyperboles.

Answer:
Context: Webinar and Ebook
Response:

Both webinars and ebooks can be used as lead magnets to attract new customers, but each offers its own unique set of benefits. Webinars are a great way to engage with an audience and provide a live demonstration of your product or service. They also provide the opportunity to answer questions and receive feedback from potential customers. On the other hand, ebooks require less effort to create and can provide in-depth information about your products and services in an easily-digestible format. They are versatile and can be shared widely, either as downloadable files or embedded on your website. Additionally, ebooks are cost-effective and can be used to promote your business to a wider audience.

Question: Compare the characteristics of two different types of lead magnets.

Answer:

1. Make a list before you shop and stick to it.
2. Buy generic items or those on sale.
3. Consider buying in bulk and dividing up items into smaller portions.
4. Look for discounts or coupons.
5. Buy fresh produce in season when they are cheaper.
6. Buy only what you need, and watch expiration dates.
7. Shop around and compare prices.

Question: Provide at least five tips on how to save money when buying groceries.
